

REPORT GENERATION IN A NETWORKED HEALTH-MONITORING SYSTEM

Abstract

A networked health-monitoring system configured to collect and process patient health-related data. A plurality of remote patient sites, includes at least one display; a data management unit configured to facilitate collection of patient health-related data; a memory and stored program instructions for generating health-monitoring related information on the display. A central server connects to the data management unit at each patient site to receive patient health-related data collected at the remote patient sites. The system produces reports, including standardized reports, from the received data.
